INTRODUCTION

This report contains example code used to conduct Phases 1 and 2 of the "Re-evaluating the Efficiency and Efficacy of Annual Census Standardized Testing for Accountability Purposes" study. In Phase 1 we prepare and format the student data in a manner that will be consistent across all states and satisfies the requirements for growth analyses using the SGP software package. With the properly formatted data, we then proceed with the Student Growth Percentiles (SGP) analyses and school level results aggregations in the Phase 2 code.

Each phase of this example analysis uses simulated state assessment data that is available in the <u>SGP</u> <u>package</u> (<u>Betebenner et al. 2022</u>) for the <u>R Software Environment</u> (<u>R Core Team 2022</u>). This data is used here so that the interested reader can also run the code as presented to reproduce the analytic workflow we have used for Phases 1 and 2 of this report.

The dataset that is produced in the Phase 1 process represents an exemplar of the data required for subsequent steps in this study. In this phase, each state requires customized code adapted to the data as provided by each state's education agency/authority. However, the end product in each state conforms to the naming and data formatting conventions described and encoded here.

Given the properly cleaned and formatted data from Phase 1, each state's student growth analyses follow a nearly identical workflow through each replicated assessment condition. Each state's results are then aggregated at the school level, again using an identical workflow.

PHASE 1 - DATA CLEANING AND PREPARATION

For this example analysis we will be using the <code>sgpData_LONG_COVID</code> data from the <code>SGPData</code> package. It includes 7 years of annual assessment data in two content areas (ELA and Mathematics). As this data is typically used for testing and research purposes with the SGP package (Betebenner et al. 2022), much of the data cleaning and formatting has already been done.

This section of the appendix assumes the user is operating with their working directory set to the state level directory (e.g., "./State_A/".

```
# setwd("./State_A")
```

LOAD PACKAGES AND CUSTOM FUNCTIONS.

The following R packages are required for the data source, cleaning and augmentation.

```
require(SGPdata)
require(data.table)
```

GENERAL DATA SETUP AND CLEANING

This example dataset comes with a "built-in" impact in 2021 related to the pandemic as well as an unperturbed version - <code>SCALE_SCORE_without_COVID_IMPACT</code>. Here we will first subset the data to include only those years needed for the study.

```
# First load and rename/remove SCALE_SCORE* variables included in the data
State_A_Data_LONG <- copy(SGPdata::sgpData_LONG_COVID)[YEAR < 2023]</pre>
```

The variables in each longitudinal data set are renamed to be consistent across all states in the study. The variable names ID, YEAR, GRADE, CONTENT_AREA and SCALE_SCORE are required SGP package conventions. The demographic variable names match the "analysis specification" document. Any extraneous variables are removed before saving.

```
setnames(
   State_A_Data_LONG,
   c("ETHNICITY", "FREE_REDUCED_LUNCH_STATUS", "ELL_STATUS", "IEP_STATUS",
        "SCHOOL_NUMBER"),
   c("Race", "EconDis", "EL", "SWD", "SchoolID")
)
State_A_Data_LONG[, Race := as.character(Race)]
State_A_Data_LONG[Race == "African American", Race := "Black"]
```

We have also decided to make schools unique by the grade levels that they serve (i.e. elementary and middle)

```
State_A_Data_LONG[, SchoolID := as.character(SchoolID)]
State_A_Data_LONG[GRADE %in% 3:5, SchoolID := paste0(SchoolID, "E")]
State_A_Data_LONG[GRADE %in% 6:8, SchoolID := paste0(SchoolID, "M")]
```

CREATE VALID CASE AND INVALIDATE DUPLICATES

The SGP package requires a variable named VALID_CASE with values set to either "VALID_CASE" or "INVALID_CASE". This is helpful in identifying cases that are problematic for any number of reasons (duplicate records, invalid ID types, missing scores or subject/grade values, etc.). Any record flagged as an "INVALID_CASE" will be excluded from any SGP analyses (but remain in the data for possible later use in other aggregations).

SAVE DATA

```
fname <- "Data/Cleaned_Data/Student_LongTestData_State_A_2016-2022_AVI.csv"
fwrite(State_A_Data_LONG, file = fname)
zip(zipfile = paste0(fname, ".zip"), files = fname, flags = "-mqj")</pre>
```

SUMMARY AND NOTES

- "State A" uses the 2016 to 2022 subset of the <code>sgpData_LONG_covid</code> dataset from the <code>sgpData_package</code>.
 - Only required variables are retained.
- Variables required by the sgp packages were renamed and formatted as necessary.
- Student demographic variables were formatted to be consistent across all states in the study.
- A valid_case variable was created and used to identify duplicate records and other problematic cases.

STUDENT GROWTH PERCENTILES ANALYSIS

This section presents and explains the code used to conduct the Student Growth Percentiles (SGP) analyses. Each simulated testing condition is applied, via R code configurations, to the same set of data, thus only producing growth measures for students with valid records in the appropriate grades, content areas and years. At the end of each condition-specific analysis, the SGP variable is renamed to indicate the simulated condition before proceeding to the next condition-specific growth analysis step. Only cohort-referenced SGPs are calculated (growth projections and targets are omitted). The goal of this step is simply to create growth percentiles and merge them into a single longitudinal dataset before aggregation and investigation of the impact non-census testing has on school accountability measures.

The code presented below is provided as an example of how the growth calculations are conducted for all states in the study. The student data for each state will be cleaned and formatted according to the study guidelines, as was done with the exemplar data from the SGP package (Betebenner et al. (2022)) in the example Phase 1 code in the previous section.

LOAD SGP PACKAGE AND MODIFY SGPSTATEDATA

The SGP package is required for all growth percentile analyses.

```
require(SGP)
require(data.table)
source("../functions/calculate_SGPs.R")
```

We will use the assessment meta-data from the "Demonstration_COVID" (abbreviated "DEMO_COVID") dataset stored in the SGPstateData object. This meta-data is required to use various functions in the SGP package.

```
SGPstateData[["State_A"]] <- SGPstateData[["DEMO_COVID"]]
```

CONDITION-SPECIFIC GROWTH ANALYSES

```
# Load cleaned, merged and formatted data
if (!exists("State_A_Data_LONG")) {
    source("../functions/freadZIP.R")
    State_A_Data_LONG <-
        freadZIP(
             "Data/Cleaned_Data/Student_LongTestData_State_A_2016-2022_AVI.csv.zip"
        )[YEAR < 2020]
} else {
    State_A_Data_LONG <- State_A_Data_LONG[YEAR < 2020]
}</pre>
```

SIMULATION CONDITION 0

In this simulation condition, we want to replicate the base condition of typical census-level testing with the base data set. Growth analyses will include grades 4 to 8, with consecutive-year assessment patterns. Students with a valid score from the previous year and grade level in their historical data will be included in the growth calculations and receive a SGP. Up to two prior scores will be used as available in the data.

LOAD AND COMBINE SGP CONFIG SCRIPTS

The growth calculation functions of the SGP software package allow users to manually specify which test progressions to run. That is, we can define the unique **year-by-grade-by-content area** cohorts of students included in each analysis.

As an example, the 2019 ELA analyses/cohorts are specified with this code:

All configurations are housed in condition specific R code scripts. Here we read these in and combine them into a single list object, state.a.config, that will be supplied to the abcSGP function.

```
source("SGP_CONFIG/Condition_0.R")
```

```
state.a.config <-
    c(ELA_2019.config,
        MATHEMATICS_2019.config,
        ELA_2018.config,
        MATHEMATICS_2018.config
)</pre>
```

CALCULATE CONDITION 0 SGPS

We use the abcSGP function from the SGP package to produce 2018 and 2019 student growth percentiles. We provide the function with the longitudinal data that was previously cleaned and formatted, as well as the list of analysis configurations and other relevant arguments to tailor the analyses to our specifications.

The SGP analysis section of the appendix assumes the user is operating with their working directory set to "./Condition_O".

```
setwd("./Condition 0")
State A SGP <-
    abcSGP(
        sgp object = State A Data LONG,
        state = "State A",
        steps = c("prepareSGP", "analyzeSGP", "combineSGP"),
        sqp.config = state.a.config,
        sgp.percentiles = TRUE,
        sgp.projections = FALSE,
        sgp.projections.lagged = FALSE,
        sgp.percentiles.baseline = FALSE,
        sgp.projections.baseline = FALSE,
        sqp.projections.lagged.baseline = FALSE,
        simulate.sgps = FALSE,
        parallel.config = list(
            BACKEND = "PARALLEL",
            WORKERS = workers
setwd("..")
```

RE-NAME AND REMOVE THE SGP VARIABLES AS NECESSARY

In order to keep all growth results in the same longitudinal dataset, we will add a Cnd_0 tag to growth related variables of interest. Extraneous variables will be removed as well before moving on to the next simulation condition. We will save the coefficient matrices from all separate analyses in case we need to replicate or compare results from this condition analysis.

SIMULATION CONDITION 1B

In this condition, students test twice per grade span (elementary and middle grades) in both subjects. Tests are administered every year in 3rd, 5th, 6th and 8th grades. Subsequently, all growth analyses will use a single prior score, and can be done with a either consecutive- or skipped-year assessment patterns.

LOAD AND COMBINE SGP CONFIG SCRIPTS

In order to avoid errors in specification of our analysis configurations, we first remove all previous configuration related objects before reading in the code for condition 1b and proceeding as before. Unlike the other simulation conditions, 1b requires *both* consecutive- and skipped-year configuration scripts.

The 2019 ELA configuration code is provided here as an example and for comparison with the code provided above for condition 0:

```
rm(list = grep(".config", ls(), value = TRUE))
source("SGP_CONFIG/Condition_lb.R")

sgp_config.clb <-
    c(ELA_2019.config,
        MATHEMATICS_2019.config,
        ELA_2018.config,
        MATHEMATICS_2018.config
)</pre>
```

CALCULATE CONDITION 1B SGPS

We again use the abcSGP function to compute the student growth percentiles for this simulation condition. Here we use the data with results from condition 0. The updated list of analysis configurations is now provided, and all other relevant arguments remain the same.

```
State_A_SGP <-
  calculate_SGPs(
    sgp_data = State_A_SGP,
    config = sgp_config.clb,
    condition = "1b",
    workers = list(TAUS = 15)
)</pre>
```

SIMULATION CONDITION 1C

In this condition, students alternate testing in each subject across grade levels. In this simulation, students in grades 3, 5, and 7 take ELA and students in grades 4, 6, 7 take mathematics each year. As with condition 1b, all growth analyses will be conditioned on a single prior score, but only skipped-year assessment patterns can be analyzed.

LOAD AND COMBINE SGP CONFIG SCRIPTS

We again remove all previous configuration related objects before reading in the condition 1c course progression code. The 2019 ELA configurations are once again provided here for comparison with other simulation conditions.

```
ELA_2019.config <- list(
    ELA.SKIP.2019 = list(
    sgp.content.areas = rep("ELA", 2),
    sgp.panel.years = c("2017", "2019"),
    sgp.grade.sequences = list(
        c("3", "5"), # Elementary Grades</pre>
```

```
)
)
```

The mathematics configurations are nearly identical to the ELA code, with the exception of the sgp.grade.sequences element, which specifies the grades 4 to 6 and grades 6 to 8 progressions. Note that this particular testing pattern means traditional elementary schools will only have growth measures for grade 5 ELA, while traditional middle schools will have growth indicators in all three grades and both content areas. The only contribution mathematics makes to a school's accountability calculation is through grade 4 proficiency (status).

```
rm(list = grep(".config", ls(), value = TRUE))
source("SGP_CONFIG/Condition_1c.R")

sgp_config.c1c <-
    c(ELA_2019.config,
        MATHEMATICS_2019.config,
        ELA_2018.config,
        MATHEMATICS_2018.config
)</pre>
```

CALCULATE CONDITION 1C SGPS

The call to thecalculate_SGPs function here performs the same calculation tasks as those made for conditions 1b. The config list specifies the cohort data to use in the growth analyses, and the condition argument will be used to create and change directories in which the analyses are run, and rename the SGP variable for this condition calculations.

```
State_A_SGP <-
  calculate_SGPs(
    sgp_data = State_A_SGP,
    config = sgp_config.clc,
    condition = "1c",
    workers = list(TAUS = 15)
)</pre>
```

SIMULATION CONDITION 2

In this condition, all students are tested every two years in each grade and subject on the state's assessments. There are two instances of this condition to simulate:

- Testing only occurs in even years (e.g., 2016, 2018, etc.)
- Testing only occurs in even years (e.g., 2017, 2019, etc.)

In both instances, in a year that testing occurs, all students are tested in every grade and subject. As with condition 1c, all growth analyses will be conditioned on a single prior score with skipped-year patterns.

LOAD AND COMBINE SGP CONFIG SCRIPTS

We again remove all previous configuration related objects before reading in the condition 2 course progression code. The 2019 ELA configurations are once again provided here for comparison with other simulation conditions.

```
rm(list = grep(".config", ls(), value = TRUE))
source("SGP_CONFIG/Condition_2.R")

sgp_config.c2 <-
    c(ELA_2019.config,
        MATHEMATICS_2019.config,
        ELA_2018.config,
        MATHEMATICS_2018.config
)</pre>
```

CALCULATE CONDITION 2 SGPS

The call to thecalculate_SGPs function here performs the same calculation tasks as those made for conditions 1b and 1c. The config list specifies the cohort data to analyze for condition 2, and the data object State_A_SGP@Data will now include the results from conditions 0 through 2 when the calculations are complete.

```
State_A_SGP <-
   calculate_SGPs(
    sgp_data = State_A_SGP,
   config = sgp_config.c2,
   condition = "2",</pre>
```

```
workers = list(TAUS = 15)
)
```

SIMULATION CONDITION 3

In this condition, all students are tested every two years at specific grade and subject on the state's assessments. As with Condition 2, there are two instances of this condition to simulate:

- Testing only occurs in even years (e.g., 2016, 2018, etc.)
- Testing only occurs in even years (e.g., 2017, 2019, etc.)

In both instances, when testing occurs, students are tested specific grades in both subject areas. As with condition 1c, all growth analyses will be conditioned on a single prior score with skipped-year patterns. ### SGP config scripts

The pattern of testing for this condition is identical to that of condition 1b, with the exception of skipping years. This means that we have already calculated the SGPs for these patterns and do not need to reanalyze the data to get these results. Instead we can simply copy the results from simulation condition 1b that use the skipped-year progressions (i.e. results for grades 5 and 8, but not 6th grade).

For the sake of completeness, however, the 2019 ELA configurations for this condition would be a subset of the condition 1b code, such as this:

USE CONDITION 1B GROWTH FOR CONDITION 3

Here we will simply copy the results from condition 1b to a new variable for condition 3. The grade 6 SGPs, which were consecutive-year (grade 5 to grade 6) will be omitted.

```
State_A_SGP@Data[
    GRADE %in% c(5, 8),
    SGP_Cnd_3 := SGP_Cnd_1b
]
```

SAVE DATA

```
if (!dir.exists("Data/Student_Growth"))
    dir.create("Data/Student_Growth", recursive = TRUE)

State_A_Data_LONG <- copy(State_A_SGP@Data)
save(State_A_Data_LONG, file = "Data/Student_Growth/State_A_Data_LONG.rda")

fname <- "Data/Student_Growth/Student_LongTestData_State_A_2016-2019_AVI.csv"
fwrite(State_A_SGP@Data, file = fname)
zip(zipfile = paste0(fname, ".zip"), files = fname, flags = "-mqj")</pre>
```

GROWTH AND ACHIEVEMENT AGGREGATIONS

To simplify the analysis and enable comparisons of results across participating states, we plan to simulate a standard "prototype" accountability model with the following features.

Reporting

- The minimum n-count for computing scores for schools and disaggregated student groups is varied depending on the simulated condition.
- The disaggregated student groups should include economically disadvantaged students, students from racial and ethnic groups, children with disabilities, and English learners, as long as they meet the minimum n-count threshold in the simulated condition.

Indicators

- **Academic achievement** is the percentage of students in the school meeting the proficiency in ELA and mathematics (as defined by the 'Proficient' cut score on the statewide assessment).
- The computation of the ELA and math proficiency rates are adjusted if a school or student group does not have at least 95% participation.
- For the other academic indicator, we apply the following rules:
 - If student-level academic growth (consecutive-year or skip-year) can be computed, then we will use it for this indicator. For consistency, we will calculate student growth percentiles (SGPs) using the student-level assessment data.
 - If student-level academic growth (consecutive-year or skip-year) cannot be computed, then we will use an improvement measure, defined as the change in average scale scores for each grade-level subject area test between administrations for the school or student group.

Summative Rating Computation

All indicator scores are standardized by transforming into z-scores. Use the following means and standard deviations (SD) for the z-score computations (of all schools and student groups):

- Academic achievement
 - Mean: mean student-level proficiency rate for the focus year
 - SD: student-level proficiency rate SD for the focus year
 - standardized by year, subject and grade.
- Other academic indicator **growth**
 - SGPs, being percentiles, can be converted directly to a standardized metric¹.
- Other academic indicator **improvement**
 - Mean: mean student-level scale score changes for the focus year, calculated separately for each grade level and subject area

¹ Ex. in R: qnorm (c(1, 10, 25, 50, 75, 90, 99)/100) gives the z-score for the 1st, 10th, 25th, ... etc., percentiles. For more on mapping percentiles on to the standard-normal distribution, see this site

- SD: SD of student-level scale scores for the focus year, calculated separately for each grade level and subject area
- standardized by year, subject and grade.
- Graduation rates, progress in ELP, and SQSS
 - Mean: mean school-level indicator scores for the focus year
 - SD: SD of school-level indicator scores for the focus year

ADDITIONAL VARIABLES FOR AGGREGATED RESULTS

A simple '1/0' binary indicator for proficiency will allow us to compute descriptive statistics (e.g., percent proficient) easily and consistently across all states included in the report.

```
## Proficient/Not (1/0) binary indicator.
State_A_Data_LONG[,
   PROFICIENCY := fcase(
        ACHIEVEMENT_LEVEL %in% c("Partially Proficient", "Unsatisfactory"), OL,
        ACHIEVEMENT_LEVEL %in% c("Advanced", "Proficient"), 1L
   )
]
```

CONDITION SPECIFIC SUMMARY TABLES - ALL STUDENTS BY SCHOOLS

NOTE TO LESLIE & EMMA These tables and aggregations are my first attempts to both interpret and implement what I've read in the "Analysis Specification" document. This is how I would approach this (sub-)Phase given my past experience in aggregating growth and achievement data.

The following is an example of a preliminary school-level aggregation table for condition 0. Each condition will have a similar table, generally with only the appropriate SGP variable substituted for SGP_Cnd_0 and changes to the inclusion criteria (YEAR, GRADE and sometimes CONTENT_AREA).

```
sch_summary_cnd_0 <-
State_A_Data_LONG[
    YEAR %in% c(2018, 2019) &
    GRADE %in% 3:8,
    .(TotalN = .N,
        ProfN = sum(PROFICIENCY == 1L),
        GrowthN = sum(!is.na(SGP_Cnd_0)),
        MGP = round(mean(SGP_Cnd_0, na.rm = TRUE), 1),
        PctProf = round(mean(PROFICIENCY, na.rm = TRUE), 3)*100
    ),
    keyby = c("SchoolID", "YEAR", "CONTENT_AREA")
]</pre>
```

Per the specifications doc, this table would be widened to have a column for each subject. This can be achieved with this code (retaining all specified descriptive statistics).

```
sch_summary_cnd_0w <-
    dcast(
    data = sch_summary_cnd_0,
    formula = SchoolID + YEAR ~ CONTENT_AREA,
    sep = "..",
    value.var = names(sch_summary_cnd_0) %w/o% key(sch_summary_cnd_0)
)
setnames(
    sch_summary_cnd_0w,
    sapply(
    names(sch_summary_cnd_0w),
    \((f) ) {
        tmp.name <- strsplit(f, "[.][.]")[[1]] |> rev() |> paste(collapse = "_")
        gsub("MATHEMATICS", "Math", tmp.name)
    }
    ) |> unlist()
)
```

Creating summary tables for the other conditions would only require changing the data records selected (year, grade and content areas as defined for each condition) and the growth variable specified in the aggregation code above. Adding in the demographic variables is a simple addition of the variable of interest into the keyby argument of the data.table aggregation. Since we are going to be doing this numerous times, we will use a custom function to create these tables, rather than copying the code for each use case.

You may notice that there are more summary calculations than what will be used (e.g., percent proficient and mean standardized scale scores). Those are included for our review - so we can easily see what a z-score, of for example 0.5, corresponds to in the actual percent proficient or mean SGP. Here are two schools from the condition 0 table:

```
school_aggregation_all_students[
   Condition == 0 & SchoolID %in% c("1001E", "3801M"), # rows to keep
   c(key(school_aggregation_all_students)[-1],
      grep("ELA", names(school_aggregation_all_students), value = TRUE)
   ), # columns to keep
   with = FALSE
] |>
   setkey(SchoolID) |> print()
```

```
## YEAR SchoolID ELA_TotalN ELA_ProfN ELA_GrowthN ELA_MGP ELA_PctProf
## 2018 1001E 120 109 73 49.740 90.833
## 2019 1001E 162 146 90 54.044 90.123
```

##	2018	3801M	49	15	44	50.727	30.612
##	2019	3801M	26	17	23	71.652	65.385

We can look at these tables in a number of ways to make sure we are getting what is expected. A simply cross-tab by year shows that many schools do not get a summary in condition 1c given the testing pattern:

```
table(school_aggregation_all_students[, .(Condition, YEAR), is.na(Math_MGP)])
```

```
fwrite(school_aggregation_all_students,
    file = "Data/School_Summaries/School_Condition_AllGrowth_AllStudents_State_A_AllYears_A
)
```

ACHIEVEMENT IMPROVEMENT AGGREGATIONS

The simulation condition 1a does not allow for growth calculations and will instead use an indicator of status improvement. This **improvement** measure is defined as the change in average scale scores for each grade-level content area test between administrations for the school or student group.

For this aggregation we will create status summaries in a similar way as the other conditions, but include all available years. Lagged values are then created and the change scores calculated.

```
# Create lagged variables (1 year lag):
setkeyv(
 sch summary cnd 1a,
 c("SchoolID", "CONTENT AREA", "YEAR", "GRADE")
cfaTools::getShiftedValues(
   sch summary cnd 1a,
    shift group = c("SchoolID", "CONTENT AREA"),
   shift variable = c("N", "MeanScore", "ScoreSD"),
   shift amount = 1L
)
# Subset the data for the two focus years:
sch summary cnd 1a <-
    sch summary cnd la[YEAR %in% c(2018, 2019)]
# Calculate Change Score (Z - effect size?)
# ELA G5 ZDiff = (ELA G5AvgScore <FYear> - ELA G5AvgScore <PYear>) / [(ELA G5StdDev <FYear>
sch summary cnd la[,
   ZDiff := (MeanScore - MeanScore LAG 1) / ((ScoreSD*N + ScoreSD LAG 1*N LAG 1)/(N + N LAG 1)
```

Here is our example school's improvement numbers

One important factor to consider with the "school improvement" indicator is the issue of "regression to the mean" that is expected to occur. There are a strong relationships between current/prior scores and change scores that may require correction:

```
cor(
  sch_summary_cnd_la[, MeanScore, ZDiff],
  use = 'na.or.complete'
) |> round(3)
```

```
## ZDiff MeanScore
## ZDiff 1.000 0.401
## MeanScore 0.401 1.000
```

```
cor(
  sch_summary_cnd_1a[, MeanScore_LAG_1, ZDiff],
  use = 'na.or.complete'
) |> round(3)
```

```
## ZDiff MeanScore_LAG_1
## ZDiff 1.00 -0.47
## MeanScore LAG 1 -0.47 1.00
```

```
sch_summary_cnd_la[,
    .(Current_Year = cor(MeanScore, ZDiff, use = 'na.or.complete'),
    Prior_Year = cor(MeanScore_LAG_1, ZDiff, use = 'na.or.complete')
),
keyby = c("YEAR", "CONTENT_AREA", "GRADE")
]
```

Per the specifications doc, here is how we could reshape this summary table so that there are separate columns for each grade and subject.

```
# Reshape by subject
sch_summary_cnd_1a[, GRADE := paste0("G", GRADE)]
setkeyv(
    sch_summary_cnd_1a,
    c("SchoolID", "CONTENT_AREA", "YEAR", "GRADE")
)
sch_summary_cnd_1a <-
    dcast(</pre>
```

If schools have both 5th and 8th grades, then take a weighted average of their _G5_ZDiff and _G8_ZDiff to create the ELA_Improve and Math_Improve variable, otherwise _Improve is equal to the grade level _G5_ZDiff or _G8_ZDiff they DO have in the school.

NOTE: This is not necessary if we break up the schools into Elementary and Middle grade only schools.

```
sch_summary_cnd_la[,
    ELA_Improve := ELA_G5_ZDiff
][
    is.na(ELA_Improve),
    ELA_Improve := ELA_G8_ZDiff
][
    !is.na(ELA_G5_ZDiff) & !is.na(ELA_G8_ZDiff),
    ELA_Improve := ((ELA_G5_ZDiff * ELA_G5_N) + (ELA_G8_ZDiff * ELA_G8_N))/(ELA_G5_N + ELA_G8_N))
[,
    Math_Improve := Math_G5_ZDiff
][
    is.na(Math_Improve),
    Math_Improve := Math_G8_ZDiff
][
    !is.na(Math_G5_ZDiff) & !is.na(Math_G8_ZDiff),
    Math_Improve := ((Math_G5_ZDiff * Math_G5_N) + (Math_G8_ZDiff * Math_G8_N))/(Math_G5_N + 1)

sch_summary_cnd_la[, (grep("ZDiff", names(sch_summary_cnd_la))) := NULL]
```

Finally, we add the Group variable to indicate this data set is for all students, and save files for each year.

```
sch_summary_cnd_1a[, Group := "All"]
setcolorder(sch_summary_cnd_1a, c("YEAR", "SchoolID", "Group"))
```

```
fwrite(sch_summary_cnd_1a[YEAR == 2018][, YEAR := NULL],
    file = "Data/School_Summaries/School_Condition_1a_State_A_2018_AVI.csv"
)
fwrite(sch_summary_cnd_1a[YEAR == 2019][, YEAR := NULL],
    file = "Data/School_Summaries/School_Condition_1a_State_A_2019_AVI.csv"
)
```

Note that the above code can be accomplished with the condlaAggrGator function:

```
sch_smry_cnd_la <- condlaAggrGator(data_table = State_A_Data_LONG)
```

This function is used below for the condition 1a summaries that are disaggregated by demographic subgroups.

SCHOOL LEVEL AGGREGATIONS BY DEMOGRAPHICS

Adding in the demographic variables is a simple addition of the variable of interest into the keyby argument of the data.table aggregation.

In order to do all the demographic summaries at once, we can combine calls to the function (rather than creating separate tables and THEN combining) using the rbindlist function from data.table. Note that the demographic subgroup indicator is changed (from the demographic variable name) to the generic "Group" for each individual table.:

All of the demographic aggregation and combination code chunks can be run for each of the SGP_Cnd* growth fields. At that point, we can then combine those objects in a wide format, stacked into a long format (with an added "Condition" variable for each table) or written to separate .csv files as described in the specification doc.

The code below creates a stacked long format version with all conditions that contain growth.

We can obtain the condition 1a by demographic subgroup using the following call to the condlaAggrGator function with group argument supplied via lapply:

```
sch_summary_cnd_la_demogs <-
lapply(
    c("Race", "EconDis", "EL", "SWD"),
    \((f) \) {
    condlaAggrGator(
        data_table = State_A_Data_LONG,
        group = f
    )
}</pre>
```

```
) |>
   rbindlist()
```

A SINGLE FILE WITH ALL AGGREGATIONS

I may be missing something about why all the various .csv files are needed for this step, but if we wanted to save all the conditions and summaries as a single file, we could do something like this (and then save as a single .csv using fwrite or similar):

SAVE THE CONDITION/YEAR SPECIFIC AGGREGATION FILES

Here is how to split up the single file created above into the individual files per the specification document.

```
school_aggregation_all[
  Condition %in% c("2", "3") & YEAR == 2018,
  Condition := paste0(Condition, "_E")
][
  Condition %in% c("2", "3") & YEAR == 2019,
  Condition := paste0(Condition, "_O")
]

fprefix <- "./Data/School_Summaries/School_Condition_"

for (cond in c("0", "1a", "1b", "1c", "2_E", "2_O", "3_E", "3_O")) {
  for (yr in 2018:2019) {
    tmp.tbl <-
        school_aggregation_all[</pre>
```

Repeat this process of combining, sub-setting and saving for condition 1a.

```
sch_summary_cnd_1a_all <-
    rbindlist(
        list(
            sch_summary_cnd_1a,
             sch_summary_cnd_1a_demogs
        )
)[
        -(grep(": No", Group)),
][,
        Group := gsub(": Yes", "", Group)
]

fwrite(sch_summary_cnd_1a_all[YEAR == 2018][, YEAR := NULL],
        file = "Data/School_Summaries/School_Condition_1a_State_A_2018_AVI.csv"
)

fwrite(sch_summary_cnd_1a_all[YEAR == 2019][, YEAR := NULL],
        file = "Data/School_Summaries/School_Condition_1a_State_A_2019_AVI.csv"
)</pre>
```

SUMMARY AND NOTES

- A binary indicator variable for proficiency status is added.
- Methods for using the data.table package for calculating school level aggregations for all students and by demographic subgroups were outlined and discussed with examples.
